Abstract. A graph is IC-planar if it admits a drawing in the plane with at most one crossing per edge and such that two pairs of crossing edges share no common end vertex. IC-planarity specializes both NIC-planarity, which allows a pair of crossing edges to share at most one vertex, and 1-planarity, where each edge may be crossed at most once. We show that there are infinitely maximal IC-planar graphs with $n$ vertices and $3n - 5$ edges and thereby prove a tight lower bound on the density of this class of graphs.

1 Introduction

A graph $G$ is maximal in a graph class $\mathcal{G}$ if no edge can be added to $G$ without violating the defining class. The density (sparsity) of $\mathcal{G}$ is an upper (lower) bound on the number of edges of maximal graphs $G \in \mathcal{G}$ with $n$ vertices. A maximal graph $G$ is densest (sparsest) in $\mathcal{G}$ if its number of edges meets the upper (lower) bound.

It is well-known that every maximal planar graph is triangulated and has $3n - 6$ edges. The densest and sparsest planar graphs coincide. This does not longer hold for 1-planar graphs, which are graphs that can be drawn with at most one crossing per edge. These graphs have recently received much interest [13]. 1-planar graphs with $n$ vertices have at most $4n - 8$ edges, and this bound is tight for $n = 8$ and all $n \geq 10$ [5, 7]. However, there are sparse maximal 1-planar graphs with less than $2.65n$ edges [10]. The best known lower bound on the sparsity of 1-planar graphs is $2.22n$ [5] and neither the upper nor the lower bound are known to be tight.

There are some subclasses of 1-planar graphs with different bounds for the density and sparsity. A graph is IC-planar (independent crossing planar) [1, 8, 14, 15] if it admits a drawing with at most one crossing per edge so that each vertex is incident to at most one crossing edge, and NIC-planar (near independent crossing planar) if two pairs of crossing edges share at most one vertex [15]. IC-planar graphs have an upper bound of $3.25n - 6$ on the number of edges, which is known as a tight bound, since there are such graphs for all $n = 4k$ and $k \geq 2$ [15]. The lower bound has not been addressed yet. The upper and lower bounds on the density of NIC-planar graphs are $\frac{12}{5}(n - 2)$ [15] and $\frac{10}{5}(n - 2)$ [3, 11] and both bounds are known to be tight for infinitely many values of $n$. Outer 1-planar graphs are another subclass of 1-planar graphs. They must admit a
1-planar embedding such that all vertices are in the outer face [2,12]. Results on the density of maximal graphs are summarized in Table 1.

Here, we establish a lower bound of $3n - 5$ on the density of IC-planar graphs and show that it is tight for all $n \geq 5$.

## 2 Density

We first prove the existence of maximal IC-planar graphs that have $n$ vertices and only $3n - 5$ edges:

**Lemma 1.** For every $n \geq 5$ there is a maximal IC-planar graph with $n$ vertices and $3n - 5$ edges.

**Proof.** As $K_5$ has exactly $3n - 5 = 10$ edges and is IC-planar, the statement trivially follows for $n = 5$. Let us hence assume in the following that $n \geq 6$. We construct a graph $G_n$ with $n$ vertices and $3n - 5$ edges as follows: $G_n$ consists of $n - 2$ vertices forming a circle $C = (v_0, v_1, \ldots, v_{n-3})$ as well as two pole vertices $p$ and $q$. For every $0 \leq i < n - 2$, $G_n$ has edges $\{v_i, p\}$ and $\{v_i, q\}$. Additionally, there is an edge $\{p, q\}$ connecting the poles. As an example, Fig. 1a depicts the graph $G_8$. Then, every vertex $v_i$, $0 \leq i < n - 2$, is incident to exactly two circle edges as well as to both $p$ and $q$, and $p$ and $q$ are each incident to $n - 1$ edges. Hence, $G_n$ has $\frac{1}{2}(4(n - 2) + 2(n - 1)) = 3n - 5$ edges. As every planar graph has at most $3n - 6$ edges, every embedding must contain at least one pair of crossing edges. Let $\mathcal{E}(G_n)$ be any IC-planar embedding of $G_n$. We will now show that $\{p, q\}$ must be crossed in $\mathcal{E}(G_n)$ and that $\mathcal{E}(G_n)$ is unique up to isomorphism.

Suppose that an edge $\{v_i, v_{i+1}\}$ crosses an edge $\{v_j, v_{j+1}\}$ in $\mathcal{E}(G_n)$ (see Fig. 1b). Due to IC-planarity, $\{v_i, p\}$, $\{v_{i+1}, p\}$, $\{v_j, q\}$, and $\{v_{j+1}, q\}$ must be planar. In consequence of the crossing, $v_j$ and $v_{j+1}$ lie on different sides of the closed path $P$ consisting of $\{v_i, p\}$, $\{v_i, v_{i+1}\}$, and $\{v_{i+1}, p\}$. Hence, either $\{v_j, q\}$ or $\{v_{j+1}, q\}$ must cross an edge of $P$, a contradiction. Thus, every crossing in $\mathcal{E}(G_n)$ must involve at least one of $p$ or $q$.

Suppose that an edge $\{v_i, p\}$ crosses an edge $\{v_j, v_{j+1}\}$ in $\mathcal{E}(G_n)$ (see Fig. 1c). By IC-planarity, $\{v_j, q\}$ and $\{v_{j+1}, q\}$ must be planar. As $n \geq 6$, there must be a vertex $v_{i'}$ adjacent to $v_i$. Furthermore, $\{v_{i'}, v_i\}$ and $\{v_{i'}, p\}$ must be planar due to IC-planarity. In consequence of the crossing, $p$ and $v_i$ however lie on different sides of the closed path $P$ consisting of $\{v_j, q\}$, $\{v_j, v_{j+1}\}$, and $\{v_{j+1}, q\}$, so either

Table 1: The density of maximal graphs on $n$ vertices.
A Note on IC-Planar Graphs

Fig. 1: Proof of Lemma 1: The graph $G_n$ for $n = 8$ (a) along with sketches of the cases where an edge $\{v_i, v_{i+1}\}$ crosses an edge $\{v_j, v_{j+1}\}$ (b), $\{v_i, p\}$ crosses an edge $\{v_j, v_{j+1}\}$ (c), and $\{v_i, p\}$ crosses an edge $\{v_j, q\}$ (d), which all yield non-IC-planar embeddings of $G_n$.

$(a)$

$(b)$

$(c)$

$(d)$

{v_l, v_i} or {v_l, p} must cross an edge of $P$, a contradiction. Thus, every crossing in $\mathcal{E}(G_n)$ must involve both $p$ and $q$.

Finally, suppose that an edge $\{v_i, p\}$ crosses an edge $\{v_j, q\}$ in $\mathcal{E}(G_n)$ (see Fig. 1d). As $n \geq 6$, there must be two further vertices $v_l \neq v_{l'}$ such that $v_l$ is adjacent to $v_i$ and $v_{l'}$ is adjacent to $v_j$. Furthermore, $\{v_l, v_{l'}\}, \{v_j, v_{j'}\}, \{v_l, p\}$, and $\{v_{l'}, q\}$ must be planar due to IC-planarity. In result of the crossing, $v_j$ and $q$ lie on different sides of the closed path $P$ consisting of $\{v_i, p\}, \{v_i, v_{l'}\}$, and $\{v_{l'}, p\}$. Thus, one of $\{v_j, v_{j'}\}$ and $\{v_{j'}, q\}$ must cross $P$, a contradiction.

Consequently, every crossing in $\mathcal{E}(G_n)$ must contain $\{p, q\}$, which in turn can only cross an edge $\{v_i, v_{i+1}\}$ for some $i$ with $0 \leq i < n - 3$ or $\{v_{n-3}, v_0\}$, as depicted, e.g., in Fig. 1a. As no edge can be added to $G_n$ and $\mathcal{E}(G_n)$ such that IC-planarity is preserved, $G_n$ is maximal.

Note that the embedding of the graphs $G_n$ from the proof of Lemma 1 are unique up to isomorphism, because $\{p, q\}$ must cross an arbitrary edge $\{v_i, v_{i+1}\}$.

Concerning the upper bound, observe that every maximal IC-planar graph with $n \geq 5$ vertices also has at least $3n - 5$ edges, as there always is at least one pair of crossing edges, i.e., it cannot be planar.
Theorem 1. For all \( n \geq 5 \), maximal IC-planar graphs with \( n \) vertices have at least \( 3n - 5 \) edges, and this bound tight.
